#### 1. Introduction

ILI9328 is a 262,144-color one-chip SoC driver for a-TFT liquid crystal display with resolution of 240RGBx320 dots, comprising a 720-channel source driver, a 320-channel gate driver, 172,800 bytes RAM for graphic data of 240RGBx320 dots, and power supply circuit.

ILI9328 has four kinds of system interfaces which are i80-system MPU interface (8-/9-/16-/18-bit bus width), VSYNC interface (system interface + VSYNC, internal clock, DB[17:0]), serial data transfer interface (SPI) and RGB 6-/16-/18-bit interface (DOTCLK, VSYNC, HSYNC, ENABLE, DB[17:0]).

In RGB interface and VSYNC interface mode, the combined use of high-speed RAM write function and widow address function enables to display a moving picture at a position specified by a user and still pictures in other areas on the screen simultaneously, which makes it possible to transfer display the refresh data only to minimize data transfers and power consumption.

ILI9328 can operate with 1.65V I/O interface voltage, and an incorporated voltage follower circuit to generate voltage levels for driving an LCD. The ILI9328 also supports a function to display in 8 colors and a sleep mode, allowing for precise power control by software and these features make the ILI9328 an ideal LCD driver for medium or small size portable products such as digital cellular phones, smart phone, PDA and PMP where long battery life is a major concern.

#### 2. Features

- Single chip solution for a liquid crystal QVGA TFT LCD display
- 240RGBx320-dot resolution capable with real 262,144 display color
- Support MVA (Multi-domain Vertical Alignment) wide view display
- Incorporate 720-channel source driver and 320-channel gate driver
- ◆ Internal 172,800 bytes graphic RAM
- High-speed RAM burst write function
- System interfaces
  - > i80 system interface with 8-/ 9-/16-/18-bit bus width
  - Serial Peripheral Interface (SPI)
  - RGB interface with 6-/16-/18-bit bus width (VSYNC, HSYNC, DOTCLK, ENABLE, DB[17:0])
  - VSYNC interface (System interface + VSYNC)
- Internal oscillator and hardware reset
- Resizing function (×1/2, ×1/4)
- Reversible source/gate driver shift direction
- Window address function to specify a rectangular area for internal GRAM access
- Abundant functions for color display control
  - γ-correction function enabling display in 262,144 colors
  - Line-unit vertical scrolling function

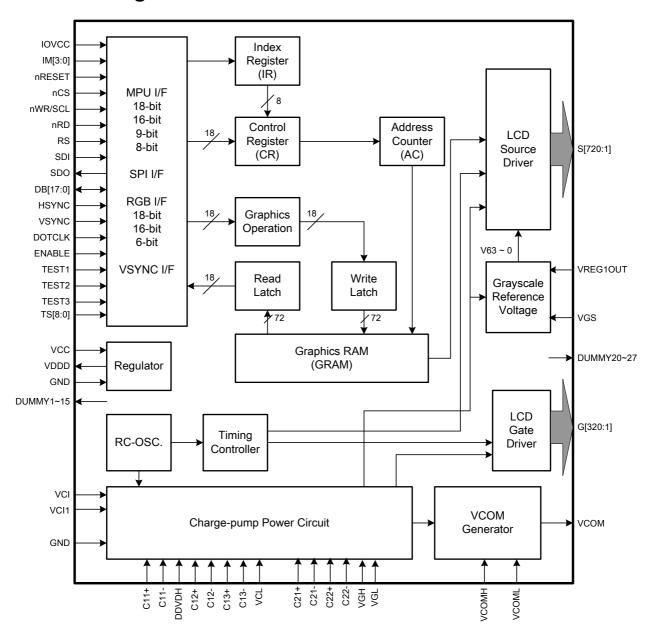

Version: 0.1

- ♦ Partial drive function, enabling partially driving an LCD panel at positions specified by user
- ◆ Incorporate step-up circuits for stepping up a liquid crystal drive voltage level up to 6 times (x6)
- Power saving functions
  - > 8-color mode
  - > standby mode
  - > sleep mode
- Low -power consumption architecture
  - Low operating power supplies:
    - IOVcc = 1.65V ~ 3.3 V (interface I/O)
    - Vci = 2.5V ~ 3.3 V (analog)
- ◆ LCD Voltage drive:
  - Source/VCOM power supply voltage
    - DDVDH GND = 4.5V ~ 6.0
    - VCL GND = -2.0V ~ -3.0V
    - $VCI VCL \le 6.0V$
  - > Gate driver output voltage
    - VGH GND = 10V ~ 20V
    - VGL GND = -5V ~ -15V
    - $VGH VGL \le 32V$
  - VCOM driver output voltage
    - VCOMH = 3.0V ~ (DDVDH-0.2)V
    - VCOML = (VCL+0.5)V ~ 0V
    - VCOMH-VCOML  $\leq 6.0$ V
- ◆ a-TFT LCD storage capacitor: Cst only

#### 5. Block Description

#### **MPU System Interface**

ILI9328 supports three system high-speed interfaces: i80-system high-speed interfaces to 8-, 9-, 16-, 18-bit parallel ports and serial peripheral interface (SPI). The interface mode is selected by setting the IM[3:0] pins.

ILI9328 has a 16-bit index register (IR), an 18-bit write-data register (WDR), and an 18-bit read-data register (RDR). The IR is the register to store index information from control registers and the internal GRAM. The WDR is the register to temporarily store data to be written to control registers and the internal GRAM. The RDR is the register to temporarily store data read from the GRAM. Data from the MPU to be written to the internal GRAM are first written to the WDR and then automatically written to the internal GRAM in internal operation. Data are read via the RDR from the internal GRAM. Therefore, invalid data are read out to the data bus when the ILI9328 read the first data from the internal GRAM. Valid data are read out after the ILI9328 performs the second read operation.

Registers are written consecutively as the register execution time.

Registers selection by system interface (8-/9-/16-/18-bit bus width)		18	0
Function	RS	nWR	nRD
Write an index to IR register	0	0	1
Read an internal status	0	1	0
Write to control registers or the internal GRAM by WDR register.	1	0	1
Read from the internal GRAM by RDR register.	1	1	0

Registers selection by the SPI system interface								
Function	R/W	RS						
Write an index to IR register	0	0						
Read an internal status	1	0						
Write to control registers or the internal GRAM by WDR register.	0	1						
Read from the internal GRAM by RDR register.	1	1						

#### Parallel RGB Interface

ILI9328 supports the RGB interface and the VSYNC interface as the external interface for displaying a moving picture. When the RGB interface is selected, display operations are synchronized with externally supplied signals, VSYNC, HSYNC, and DOTCLK. In RGB interface mode, data (DB17-0) are written in synchronization with these signals according to the polarity of enable signal (ENABLE) to prevent flicker on display while updating display data.

In VSYNC interface mode, the display operation is synchronized with the internal clock except frame synchronization, where the operation is synchronized with the VSYNC signal. Display data are written to the internal GRAM via the system interface. In this case, there are constraints in speed and method in writing data to the internal RAM. For details, see the "External Display Interface" section. The ILI9328 allows for switching between the external display interface and the system interface by instruction so that the optimum interface is selected for the kind of picture to be displayed on the screen (still and/or moving picture(s)). The RGB

interface, by writing all display data to the internal RAM, allows for transferring data only when updating the frames of a moving picture, contributing to low power requirement for moving picture display.

#### Address Counter (AC)

The address counter (AC) gives an address to the internal GRAM. When the index of the register for setting a RAM address in the AC is written to the IR, the address information is sent from the IR to the AC. As writing data to the internal GRAM, the address in the AC is automatically updated plus or minus 1. The window address function enables writing data only in the rectangular area arbitrarily set by users on the GRAM.

#### **Graphics RAM (GRAM)**

GRAM is graphics RAM storing bit-pattern data of 172,820 (240 x 320x 18/8) bytes with 18 bits per pixel.

#### **Grayscale Voltage Generating Circuit**

The grayscale voltage generating circuit generates a liquid crystal drive voltage according to grayscale data set in the  $\gamma$ -correction register to display in 262,144 colors. For details, see the " $\gamma$ -Correction Register" section.

#### **Timing Controller**

The timing generator generates a timing signal for operation of internal circuits such as the internal GRAM. The timing for the display operation such as RAM read operation and the timing for the internal operation such as access from the MPU are generated in the way not to interfere each other.

#### Oscillator (OSC)

ILI9328 generates RC oscillation with an internal oscillation resistor. The frame rate is adjusted by the register setting.

#### **LCD Driver Circuit**

The LCD driver circuit of ILI9328 consists of a 720-output source driver (S1  $\sim$  S720) and a 320-output gate driver (G1 $\sim$ G320). Display pattern data are latched when the 720<sup>th</sup> bit data are input. The latched data control the source driver and generate a drive waveform. The gate driver for scanning gate lines outputs either VGH or VGL level. The shift direction of 720 source outputs from the source driver is set with the SS bit and the shift direction of gate outputs from the gate driver is set with the GS bit. The scan mode by the gate driver is set with the SM bit. These bits allow setting an appropriate scan method for an LCD module.

#### **LCD Driver Power Supply Circuit**

The LCD drive power supply circuit generates the voltage levels VREG10UT, VGH, VGL and Vcom for driving an LCD.

#### 6. System Interface

#### 6.1. Interface Specifications

ILI9328 has the system interface to read/write the control registers and display graphics memory (GRAM), and the RGB Input Interface for displaying a moving picture. User can select an optimum interface to display the moving or still picture with efficient data transfer. All display data are stored in the GRAM to reduce the data transfer efforts and only the updating data is necessary to be transferred. User can only update a sub-range of GRAM by using the window address function.

ILI9328 also has the RGB interface and VSYNC interface to transfer the display data without flicker the moving picture on the screen. In RGB interface mode, the display data is written into the GRAM through the control signals of ENABLE, VSYNC, HSYNC, DOTCLK and data bus DB[17:0].

In VSYNC interface mode, the internal display timing is synchronized with the frame synchronization signal (VSYNC). The VSYNC interface mode enables to display the moving picture display through the system interface. In this case, there are some constraints of speed and method to write data to the internal RAM.

ILI9328 operates in one of the following 4 modes. The display mode can be switched by the control register. When switching from one mode to another, refer to the sequences mentioned in the sections of RGB and VSYNC interfaces.

Operation Mode	RAM Access Setting (RM)	Display Operation Mode (DM[1:0])
Internal operating clock only (Displaying still pictures)	System interface (RM = 0)	Internal operating clock (DM[1:0] = 00)

#### 6.2. Input Interfaces

The following are the system interfaces available with the ILI9328. The interface is selected by setting the IM[3:0] pins. The system interface is used for setting registers and GRAM access.

IM3	IM2	IM1	IM0/ID	Interface Mode	DB Pin
0	0	0	0	Setting invalid	
0	0	0	1	Setting invalid	
0	0	1	0	i80-system 16-bit interface	DB[17:10], DB[8:1]
0	0	1	1	i80-system 8-bit interface	DB[17:10]

#### 6.2.2. i80/16-bit System Interface

The i80/16-bit system interface is selected by setting the IM[3:0] as "0010" levels. The 262K or 65K color can be display through the 16-bit MPU interface. When the 262K color is displayed, two transfers (1<sup>st</sup> transfer: 2 bits, 2<sup>nd</sup> transfer: 16 bits or 1<sup>st</sup> transfer: 16 bits, 2<sup>nd</sup> transfer: 2 bits) are necessary for the 16-bit CPU interface.

#### 6.2.3. i80/9-bit System Interface

The i80/9-bit system interface is selected by setting the IM[3:0] as "1011" and the DB17~DB9 pins are used to transfer the data. When writing the 16-bit register, the data is divided into upper byte (8 bits and LSB is not used) lower byte and the upper byte is transferred first. The display data is also divided in upper byte (9 bits) and lower byte, and the upper byte is transferred first. The unused DB[8:0] pins must be tied to GND.

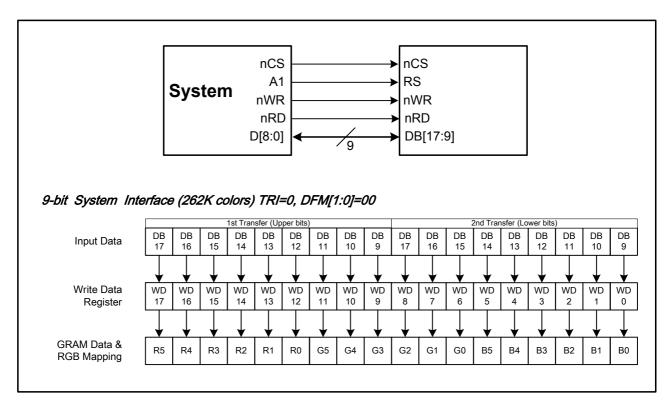

Figure 4 9-bit System Interface Data Format

#### 6.2.4. i80/8-bit System Interface

The i80/8-bit system interface is selected by setting the IM[3:0] as "0011" and the DB17~DB10 pins are used to transfer the data. When writing the 16-bit register, the data is divided into upper byte (8 bits and LSB is not used) lower byte and the upper byte is transferred first. The display data is also divided in upper byte (8 bits) and lower byte, and the upper byte is transferred first. The written data is expanded into 18 bits internally (see the figure below) and then written into GRAM. The unused DB[9:0] pins must be tied to GND.

#### Data transfer synchronization in 8/9-bit bus interface mode

ILI9328 supports a data transfer synchronization function to reset upper and lower counters which count the transfers numbers of upper and lower byte in 8/9-bit interface mode. If a mismatch arises in the numbers of transfers between the upper and lower byte counters due to noise and so on, the "00"h register is written 4 times consecutively to reset the upper and lower counters so that data transfer will restart with a transfer of upper byte. This synchronization function can effectively prevent display error if the upper/lower counters are periodically reset.

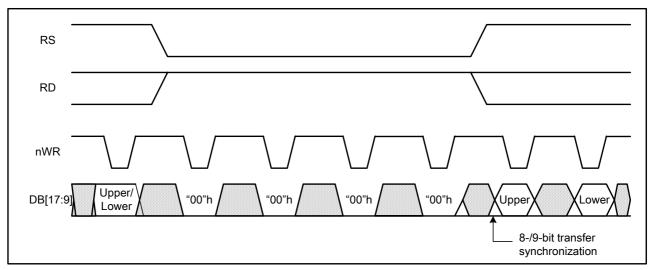

Figure 6 Data Transfer Synchronization in 8/9-bit System Interface

#### 6.3. Serial Peripheral Interface (SPI)

The Serial Peripheral Interface (SPI) is selected by setting the IM[3:0] pins as "010x" level. The chip select pin

Version: 0.1

(nCS), the serial transfer clock pin (SCL), the serial data input pin (SDI) and the serial data output pin (SDO) are used in SPI mode. The ID pin sets the least significant bit of the identification code. The DB[17:0] pins, which are not used, must be tied to GND.

The SPI interface operation enables from the falling edge of nCS and ends of data transfer on the rising edge of nCS. The start byte is transferred to start the SPI interface and the read/write operation and RS information are also included in the start byte. When the start byte is matched, the subsequent data is received by ILI9328.

The seventh bit of start byte is RS bit. When RS = "0", either index write operation or status read operation is executed. When RS = "1", either register write operation or RAM read/write operation is executed. The eighth bit of the start byte is used to select either read or write operation (R/W bit). Data is written when the R/W bit is "0" and read back when the R/W bit is "1".

After receiving the start byte, ILI9328 starts to transfer or receive the data in unit of byte and the data transfer starts from the MSB bit. All the registers of the ILI9328 are 16-bit format and receive the first and the second byte datat as the upper and the lower eight bits of the 16-bit register respectively. In SPI mode, 5 bytes dummy read is necessary and the valid data starts from 6<sup>th</sup> byte of read back data.

#### **Start Byte Format**

Transferred bits	S	1	2	3	4	5	6	7	8
Start byte format	Transfer start			Device	ID code			RS	R/W
		0	1	1	1	0	ID	1/0	1/0

Note: ID bit is selected by setting the IMO/ID pin.

#### RS and R/W Bit Function

#### 6.4. VSYNC Interface

ILI9328 supports the VSYNC interface in synchronization with the frame-synchronizing signal VSYNC to display the moving picture with the i80 system interface. When the VSYNC interface is selected to display a moving picture, the minimum GRAM update speed is limited and the VSYNC interface is enabled by setting DM[1:0] = "10" and RM = "0".

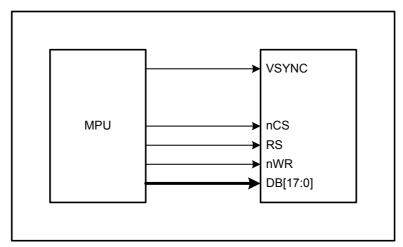

Figure 10 Data transmission through VSYNC interface)

In the VSYNC mode, the display operation is synchronized with the internal clock and VSYNC input and the frame rate is determined by the pulse rate of VSYNC signal. All display data are stored in GRAM to minimize total data transfer required for moving picture display.

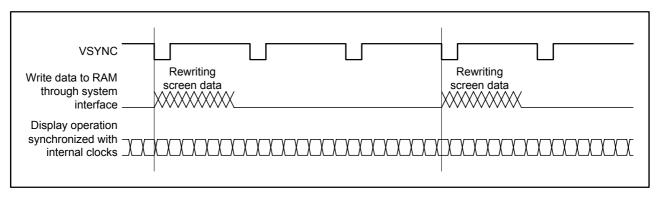

Figure 11 Moving picture data transmission through VSYNC interface

Page 33 of 106

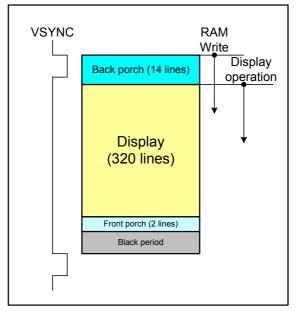

Figure 12 Operation through VSYNC Interface

The VSYNC interface has the minimum speed limitation of writing data to the internal GRAM via the system interface, which are calculated from the following formula.

Internal clock frequency (fosc.) [Hz] = FrameFrequency x (DisplayLine (NL) + FrontPorch (FP) + BackPorch (BP)) x ClockCyclePerLines (RTN) x FrequencyFluctuation.

Note: When the RAM write operation does not start from the falling edge of VSYNC, the time from the falling edge of VSYNC until the start of RAM write operation must also be taken into account.

An example of minimum GRAM writing speed and internal clock frequency in VSYNC interface mode is as below.

#### [Example]

Display size: 240 RGB × 320 lines Lines: 320 lines (NL = 100111) Back porch: 14 lines (BP = 1110) Front porch: 2 lines (FP = 0010)

Frame frequency: 60 Hz Frequency fluctuation: 10%

Internal oscillator clock (fosc.) [Hz] =  $60 \times [320+2+14] \times 16 \text{ clocks } \times (1.1/0.9) = 394 \text{KHz}$ 

When calculate the internal clock frequency, the oscillator variation is needed to be taken into consideration. In the above example, the calculated internal clock frequency with ±10% margin variation is considered and ensures to complete the display operation within one VSYNC cycle. The causes of frequency variation come from fabrication process of LSI, room temperature, external resistors and VCI voltage variation.

Minimum speed for RAM writing [Hz] > 240 x 320 x 394K / [ (14 + 320 - 2) lines x 16clocks] = 5.7 MHz

The above theoretical value is calculated based on the premise that the ILI9328 starts to write data into the internal GRAM on the falling edge of VSYNC. There must at least be a margin of 2 lines between the physical display line and the GRAM line address where data writing operation is performed. The GRAM write speed of 5.7MHz or more will guarantee the completion of GRAM write operation before the ILI9328 starts to display the GRAM data on the screen and enable to rewrite the entire screen without flicker.

#### Notes in using the VSYNC interface

- 1. The minimum GRAM write speed must be satisfied and the frequency variation must be taken into consideration.
- 2. The display frame rate is determined by the VSYNC signal and the period of VSYNC must be longer than the scan period of an entire display.
- 3. When switching from the internal clock operation mode (DM[1:0] = "00") to the VSYNC interface mode or inversely, the switching starts from the next VSYNC cycle, i.e. after completing the display of the frame.
- 4. The partial display, vertical scroll, and interlaced scan functions are not available in VSYNC interface mode and set the AM bit to "0" to transfer display data.

#### 6.5. RGB Input Interface

The RGB Interface mode is available for ILI9328 and the interface is selected by setting the RIM[1:0] bits as following table.

RIM1	RIM0	RGB Interface	DB pins
0	0	18-bit RGB Interface	DB[17:0]
0	1	16-bit RGB Interface	DB[17:13], DB[11:1]

#### 6.5.1. RGB Interface

The display operation via the RGB interface is synchronized with the VSYNC, HSYNC, and DOTCLK signals. The RGB interface transfers the updated data to GRAM with the high-speed write function and the update area is defined by the window address function. The back porch and front porch are used to set the RGB interface timing.

The timing chart of 6-bit RGB interface mode is shown as follows.

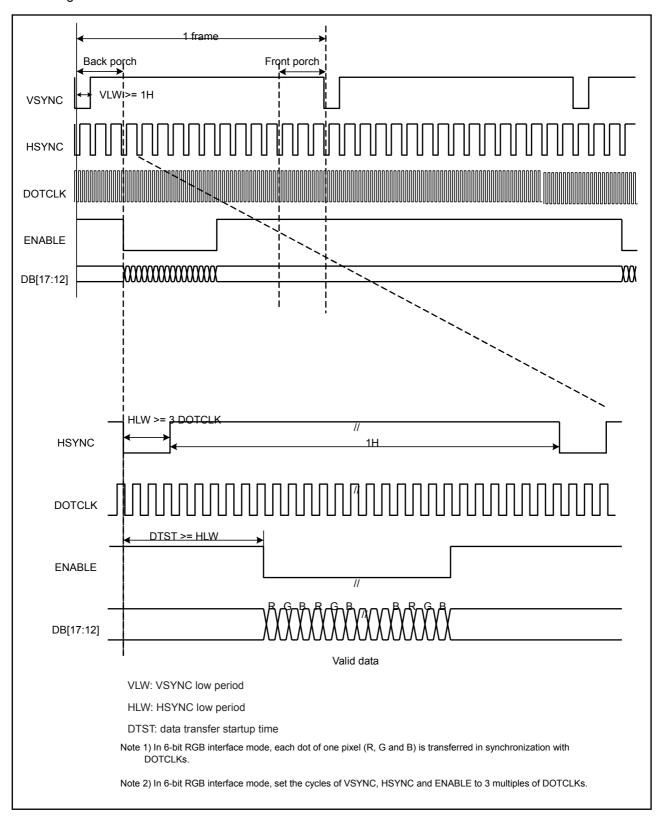

Figure 17 Timing chart of signals in 6-bit RGB interface mode

#### 6.5.3. Moving Picture Mode

ILI9328 has the RGB interface to display moving picture and incorporates GRAM to store display data, which has following merits in displaying a moving picture.

- The window address function defined the update area of GRAM.
- Only the moving picture area of GRAM is updated.
- When display the moving picture in RGB interface mode, the DB[17:0] can be switched as system interface to update still picture area and registers, such as icons.

#### RAM access via a system interface in RGB-I/F mode

ILI9328 allows GRAM access via the system interface in RGB interface mode. In RGB interface mode, data are written to the internal GRAM in synchronization with DOTCLK and ENABLE signals. When write data to the internal GRAM by the system interface, set ENABLE to terminate the RGB interface and switch to the system interface to update the registers (RM = "0") and the still picture of GRAM. When restart RAM access in RGB interface mode, wait one read/write cycle and then set RM = "1" and the index register to R22h to start accessing RAM via the RGB interface. If RAM accesses via two interfaces conflicts, there is no guarantee that data are written to the internal GRAM.

The following figure illustrates the operation of the ILI9328 when displaying a moving picture via the RGB interface and rewriting the still picture RAM area via the system interface.

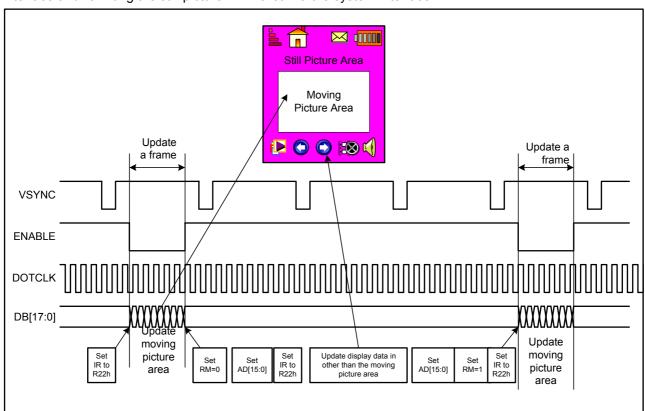

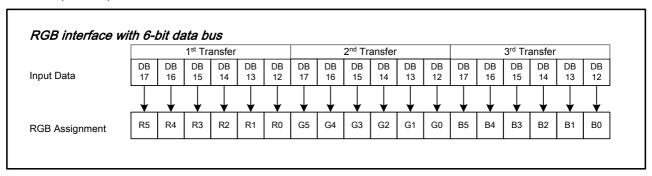

Figure 18 Example of update the still and moving picture

#### 6.5.4. 6-bit RGB Interface

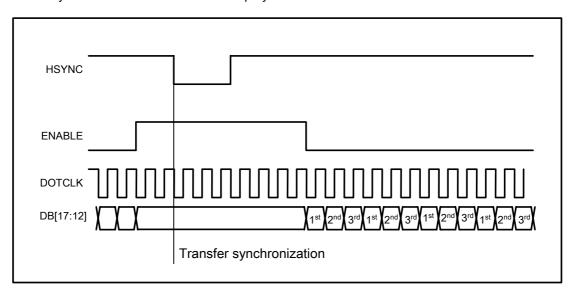

The 6-bit RGB interface is selected by setting the RIM[1:0] bits to "10". The display operation is synchronized with VSYNC, HSYNC, and DOTCLK signals. Display data are transferred to the internal GRAM in synchronization with the display operation via 6-bit RGB data bus (DB[17:12]) according to the data enable signal (ENABLE). Unused pins (DB[11:0]) must be fixed at GND level. Registers can be set by the system interface (i80/SPI).

#### Data transfer synchronization in 6-bit RGB interface mode

ILI9328 has data transfer counters to count the first, second, third data transfers in 6-bit RGB interface mode. The transfer counter is always reset to the state of first data transfer on the falling edge of VSYNC. If a mismatch arises in the number of each data transfer, the counter is reset to the state of first data transfer at the start of the frame (i.e. on the falling edge of VSYNC) to restart data transfer in the correct order from the next frame. This function is expedient for moving picture display, which requires consecutive data transfer in light of minimizing effects from failed data transfer and enabling the system to return to a normal state.

Note that internal display operation is performed in units of pixels (RGB: taking 3 inputs of DOTCLK). Accordingly, the number of DOTCLK inputs in one frame period must be a multiple of 3 to complete data transfer correctly. Otherwise it will affect the display of that frame as well as the next frame.

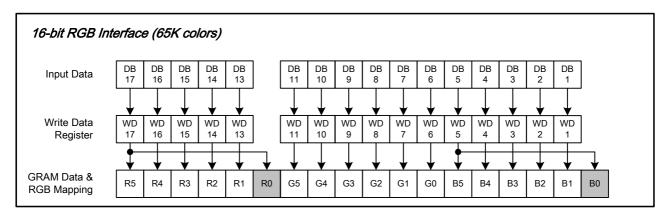

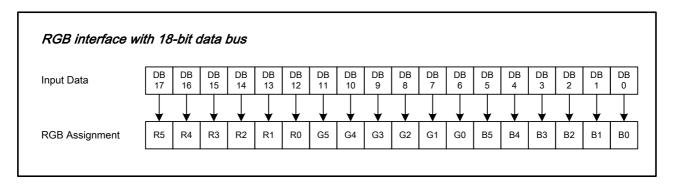

#### 6.5.5. 16-bit RGB Interface

The 16-bit RGB interface is selected by setting the RIM[1:0] bits to "01". The display operation is synchronized with VSYNC, HSYNC, and DOTCLK signals. Display data are transferred to the internal RAM in synchronization with the display operation via 16-bit RGB data bus (DB17-13, DB11-1) according to the data enable signal (ENABLE). Registers are set only via the system interface.

#### 6.5.6. 18-bit RGB Interface

The 18-bit RGB interface is selected by setting the RIM[1:0] bits to "00". The display operation is synchronized with VSYNC, HSYNC, and DOTCLK signals. Display data are transferred to the internal RAM in synchronization with the display operation via 18-bit RGB data bus (DB[17:0]) according to the data enable signal (ENABLE). Registers are set only via the system interface.

#### Notes in using the RGB Input Interface

1. The following are the functions not available in RGB Input Interface mode.

Function	RGB interface	180 system interface
Partial display	Not available	Available
Scroll function	Not available	Available
Interlaced scan	Not available	Available

- 2. VSYNC, HSYNC, and DOTCLK signals must be supplied throughout a display operation period.
- 3. The periods set with the NO[1:0] bits (gate output non-overlap period), STD[1:0] bits (source output delay period) and EQ[1:0] bits (equalization period) are not based on the internal clock but based on DOTCLK in

RGB interface mode.

- 4. In 6-bit RGB interface mode, each of RGB dots is transferred in synchronization with a DOTCLK input. In other words, it takes 3 DOTCLK inputs to transfer one pixel. Be sure to complete data transfer in units of 3 DOTCLK inputs in 6-bit RGB interface mode.
- 5. In 6-bit RGB interface mode, data of one pixel, which consists of RGB dots, are transferred in units of 3 DOTCLK. Accordingly, set the cycle of each signal in 6-bit interface mode (VSYNC, HSYNC, ENABLE, DB[17:0]) to contain DOTCLK inputs of a multiple of 3 to complete data transfer in units of pixels.
- 6. When switching from the internal operation mode to the RGB Input Interface mode, or the other way around, follow the sequence below.
- 7. In RGB interface mode, the front porch period continues until the next VSYNC input is detected after drawing one frame.
- 8. In RGB interface mode, a RAM address (AD[15:0]) is set in the address counter every frame on the falling edge of VSYNC.

### 7. Register Descriptions

#### 7.1. Registers Access

ILI9328 adopts 18-bit bus interface architecture for high-performance microprocessor. All the functional blocks of ILI9328 starts to work after receiving the correct instruction from the external microprocessor by the 18-, 16-, 9-, 8-bit interface. The index register (IR) stores the register address to which the instructions and display data will be written. The register selection signal (RS), the read/write signals (nRD/nWR) and data bus D17-0 are used to read/write the instructions and data of ILI9328. The registers of the ILI9328 are categorized into the following groups.

- 1. Specify the index of register (IR)
- 2. Read a status
- 3. Display control
- 4. Power management Control
- 5. Graphics data processing
- 6. Set internal GRAM address (AC)
- 7. Transfer data to/from the internal GRAM (R22)
- 8. Internal grayscale y-correction (R30 ~ R39)

Normally, the display data (GRAM) is most often updated, and in order since the ILI9328 can update internal GRAM address automatically as it writes data to the internal GRAM and minimize data transfer by using the window address function, there are fewer loads on the program in the microprocessor. As the following figure shows, the way of assigning data to the 16 register bits (D[15:0]) varies for each interface. Send registers in accordance with the following data transfer format.

**SS:** Select the shift direction of outputs from the source driver.

When SS = 0, the shift direction of outputs is from S1 to S720

When SS = 1, the shift direction of outputs is from S720 to S1.

In addition to the shift direction, the settings for both SS and BGR bits are required to change the assignment of R, G, B dots to the source driver pins.

To assign R, G, B dots to the source driver pins from S1 to S720, set SS = 0.

To assign R, G, B dots to the source driver pins from S720 to S1, set SS = 1.

When changing SS or BGR bits, RAM data must be rewritten.

**SM:** Sets the gate driver pin arrangement in combination with the GS bit (R60h) to select the optimal scan mode for the module.

W	1		TRI	DFM	0	BGR	0	0	0	0	ORG	0	I/D1	I/D0	AM	0	0	0

AM Control the GRAM update direction.

When AM = "0", the address is updated in horizontal writing direction.

When AM = "1", the address is updated in vertical writing direction.

When a window area is set by registers R50h ~R53h, only the addressed GRAM area is updated based on I/D[1:0] and AM bits setting.

**I/D[1:0]** Control the address counter (AC) to automatically increase or decrease by 1 when update one pixel display data. Refer to the following figure for the details.

	I/D[1:0] = 00 Horizontal : decrement Vertical : decrement	I/D[1:0] = 01 Horizontal : increment Vertical : decrement	I/D[1:0] = 10 Horizontal : decrement Vertical : increment	I/D[1:0] = 11 Horizontal : increment Vertical : increment

AM = 1 Vertical				B

Figure 25 GRAM Access Direction Setting

**ORG** Moves the origin address according to the ID setting when a window address area is made. This function is enabled when writing data with the window address area using high-speed RAM write.

ORG = "0": The origin address is not moved. In this case, specify the address to start write operation according to the GRAM address map within the window address area.

ORG = "1": The original address "00000h" moves according to the I/D[1:0] setting.

Notes: 1. When ORG=1, only the origin address address"00000h" can be set in the RAM address set registers R20h, and R21h.

2. In RAM read operation, make sure to set ORG=0.

**BGR** Swap the R and B order of written data.

BGR="0": Follow the RGB order to write the pixel data.

BGR="1": Swap the RGB data to BGR in writing into GRAM.

**TRI** When TRI = "1", data are transferred to the internal RAM in 8-bit x 3 transfers mode via the 8-bit interface. It is also possible to send data via the 16-bit interface or SPI in the transfer mode that realizes display in 262k colors in combination with DFM bits. When not using these interface modes, be sure to set TRI = "0".

**DFM** Set the mode of transferring data to the internal RAM when TRI = "1". See the following figures for details.

**RSZ[1:0]** Sets the resizing factor.

When the RSZ bits are set for resizing, the ILI9328 writes the data according to the resizing factor so that the original image is displayed in horizontal and vertical dimensions, which are contracted according to the factor respectively. See "Resizing function".

RCH[1:0] Sets the number of remainder pixels in horizontal direction when resizing a picture.

By specifying the number of remainder pixels by RCH bits, the data can be transferred without taking the reminder pixels into consideration. Make sure that RCH = 2'h0 when not using the resizing function (RSZ = 2'h0) or there are no remainder pixels.

**RCV[1:0]** Sets the number of remainder pixels in vertical direction when resizing a picture.

By specifying the number of remainder pixels by RCV bits, the data can be transferred without taking the reminder pixels into consideration. Make sure that RCV = 2'h0 when not using the resizing function (RSZ = 2'h0) or there are no remainder pixels.

**D[1:0]** Set D[1:0]="11" to turn on the display panel, and D[1:0]="00" to turn off the display panel.

A graphics display is turned on the panel when writing D1 = "1", and is turned off when writing D1 = "0".

When writing D1 = "0", the graphics display data is retained in the internal GRAM and the ILI9328 displays the data when writing D1 = "1". When D1 = "0", i.e. while no display is shown on the panel, all source outputs becomes the GND level to reduce charging/discharging current, which is generated within the LCD while driving liquid crystal with AC voltage.

When the display is turned off by setting D[1:0] = "01", the ILI9328 continues internal display operation. When the display is turned off by setting D[1:0] = "00", the ILI9328 internal display operation is halted completely. In combination with the GON, DTE setting, the D[1:0] setting controls display ON/OFF.

Note: 1. data write operation from the microcontroller is performed irrespective of the setting of D[1:0] bits.

- 2. The D[1:0] setting is valid on both 1<sup>st</sup> and 2<sup>nd</sup> displays.
- 3. The non-lit display level from the source output pins is determined by instruction (PTS).

**CL** When CL = "1", the 8-color display mode is selected.

#### **BASEE**

Base image display enable bit. When BASEE = "0", no base image is displayed. The ILI9328 drives liquid crystal at non-lit display level or displays only partial images. When BASEE = "1", the base image is displayed. The D[1:0] setting has higher priority over the BASEE setting.

#### PTDE[1:0]

Partial image 2 and Partial image 1 enable bits

PTDE1/0 = 0: turns off partial image. Only base image is displayed.

PTDE1/0 = 1: turns on partial image. Set the base image display enable bit to 0 (BASEE = 0).

0	V63	V0
1	V0	V63

**GS:** Sets the direction of scan by the gate driver in the range determined by SCN[4:0] and NL[4:0]. The scan direction determined by GS = 0 can be reversed by setting GS = 1.

When GS = 0, the scan direction is from G1 to G320.

When GS = 1, the scan direction is from G320 to G1

**REV:** Enables the grayscale inversion of the image by setting REV=1.

VLE: Vertical scroll display enable bit. When VLE = 1, the ILI9328 starts displaying the base image from the line (of the physical display) determined by VL[8:0] bits. VL[8:0] sets the amount of scrolling, which is the number of lines to shift the start line of the display from the first line of the physical display. Note that the partial image display position is not affected by the base image scrolling.

The vertical scrolling is not available in external display interface operation. In this case, make sure to

set VLE = "0".

VLE	Base Image Display
0	Fixed
1	Enable Scrolling

**VL[8:0]:** Sets the scrolling amount of base image. The base image is scrolled in vertical direction and displayed from the line determined by VL[8:0]. Make sure that VL[8:0]  $\leq 320$ .

### 10. Window Address Function

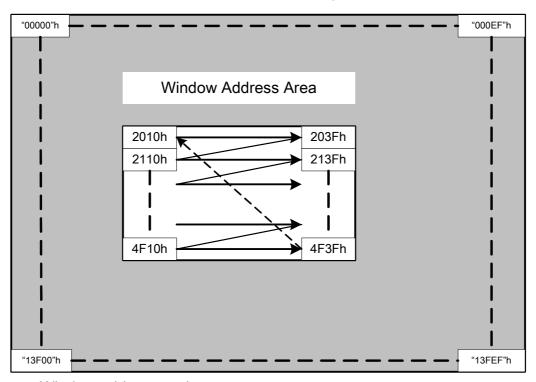

The window address function enables writing display data consecutively in a rectangular area (a window address area) made on the internal RAM. The window address area is made by setting the horizontal address register (start: HSA[7:0], end: HEA[7:0] bits) and the vertical address register (start: VSA[8:0], end: VEA[8:0] bits). The AM bit sets the transition direction of RAM address (either increment or decrement). These bits enable the ILI9328 to write data including image data consecutively not taking data wrap positions into account.

The window address area must be made within the GRAM address map area. Also, the GRAM address bits (RAM address set register) must be an address within the window address area.

[Window address setting area]

## 11. Gamma Correction

ILI9328 incorporates the  $\gamma$ -correction function to display 262,144 colors for the LCD panel. The  $\gamma$ -correction is performed with 3 groups of registers determining eight reference grayscale levels, which are gradient adjustment, amplitude adjustment and fine-adjustment registers for positive and negative polarities, to make ILI9328 available with liquid crystal panels of various characteristics.

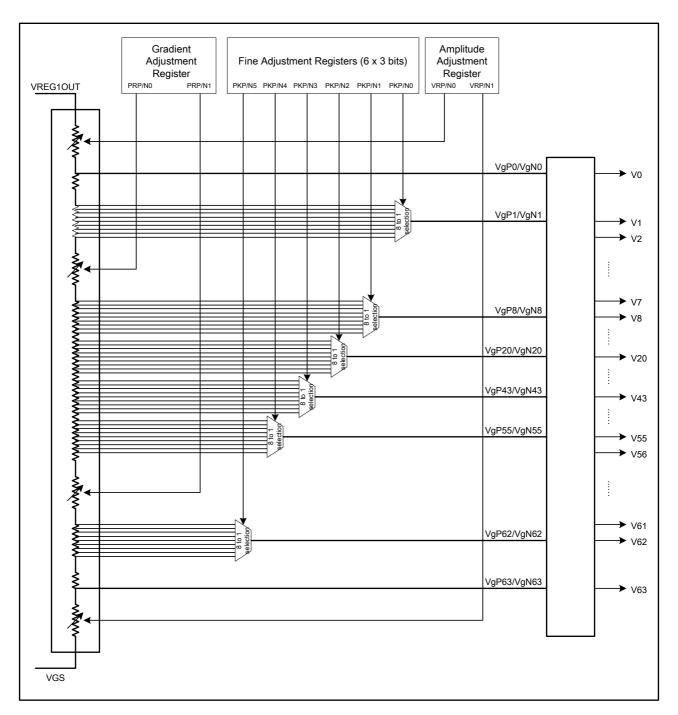

Figure 36 Grayscale Voltage Generation

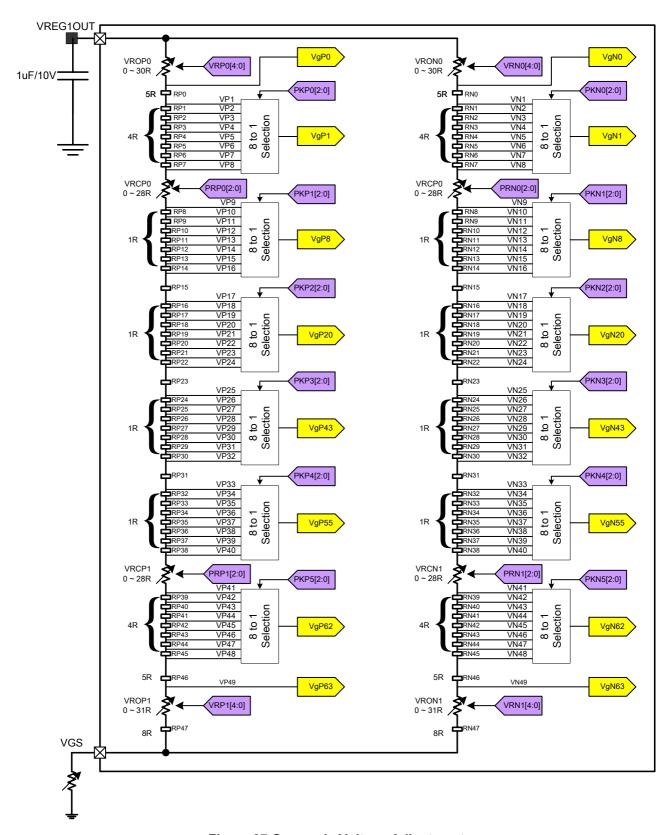

Figure 37 Grayscale Voltage Adjustment

#### 1. Gradient adjustment registers

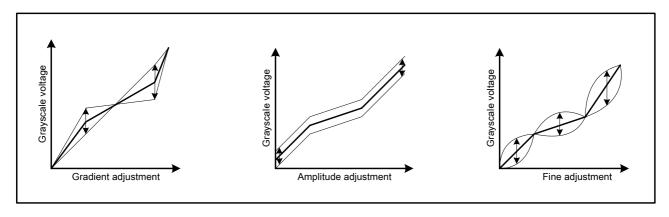

The gradient adjustment registers are used to adjust the gradient of the curve representing the relationship between the grayscale and the grayscale reference voltage level. To adjust the gradient, the resistance values of variable resistors in the middle of the ladder resistor are adjusted by registers PRP0[2:0]/PRN0[2:0], PRP1[2:0]/PRN1[2:0]. The registers consist of positive and negative polarity registers, allowing asymmetric drive.

#### 2. Amplitude adjustment registers

The amplitude adjustment registers, VRP0[3:0]/VRN0[3:0], VRP1[4:0]/VRN1[4:0], are used to adjust the amplitude of grayscale voltages. To adjust the amplitude, the resistance values of variable resistors at the top and bottom of the ladder resistor are adjusted. Same as the gradient registers, the amplitude adjustment registers consist of positive and negative polarity registers.

#### 3. Fine adjustment registers

The fine adjustment registers are used to fine-adjust grayscale voltage levels. To fine-adjust grayscale voltage levels, fine adjustment registers adjust the reference voltage levels, 8 levels for each register generated from the ladder resistor, in respective 8-to-1 selectors. Same with other registers, the fine adjustment registers consist of positive and negative polarity registers.

**Figure 38 Gamma Curve Adjustment**

	KP4 [2:0]	KN4 [2:0]	8-to-1 selector (voltage level of grayscale 55)
	KP5 [2:0]	KN5 [2:0]	8-to-1 selector (voltage level of grayscale 62)

#### Ladder resistors and 8-to-1 selector Block configuration

The reference voltage generating block consists of two ladder resistor units including variable resistors and 8-to-1 selectors. Each 8-to-1 selector selects one of the 8 voltage levels generated from the ladder resistor unit to output as a grayscale reference voltage. Both variable resistors and 8-to-1 selectors are controlled according to the  $\gamma$ -correction registers. This unit has pins to connect a volume resistor externally to compensate differences in various characteristics of panels.

#### Variable resistors

ILI9328 uses variable resistors of the following three purposes: gradient adjustment (VRCP(N)0/VRCP(N)1); amplitude adjustment (1) (VROP(N)0); and the amplitude adjustment (2) (VROP(N)1). The resistance values of these variable resistors are set by gradient adjustment registers and amplitude adjustment registers as follows.

Gradient ad	Gradient adjustment		justment (1)	Amplitude adjustment (2)	
PRP(N)0/1[2:0]	VRCP(N)0	VRP(N)0[3:0] VROP(N)0		VRP(N)1[4:0]	VROP(N)1

#### 8-to-1 selectors

The 8-to-1 selector selects one of eight voltage levels generated from the ladder resistor unit according to the fine adjustment register and output the selected voltage level as a reference grayscale voltage (VgP(N)1~6). The table below shows the setting in the fine adjustment register and the selected voltage levels for respective reference grayscale voltages.

### 12.5. Voltage Generation

The pattern diagram for setting the voltages and the waveforms of the voltages of the ILI9328 are as follows.

**Figure 45 Voltage Configuration Diagram** 

Note: The DDVDH, VGH, VGL, and VCL output voltage levels are lower than their theoretical levels (ideal voltage levels) due to current consumption at respective outputs. The voltage levels in the following relationships (DDVDH - VREG1OUT ) > 0.2V and (VCOML - VCL) > 0.5V are the actual voltage levels. When the alternating cycles of VCOM are set high (e.g. the polarity inverts every line cycle), current consumption is large. In this case, check the voltage before use.

## 12.7. Partial Display Function

The ILI9328 allows selectively driving two partial images on the screen at arbitrary positions set in the screen drive position registers.

The following example shows the setting for partial display function:

	Base Image Display Setting

## 12.8. Resizing Function

ILI9328 supports resizing function (x1/2, x1/4), which is performed when writing image data to GRAM. The resizing function is enabled by setting a window address area and the RSZ bit which represents the resizing factor (x1/2, x1/4) of image. The resizing function allows the system to transfer the original-size image data into the GRAM with resized image data.

Page 98 of 106

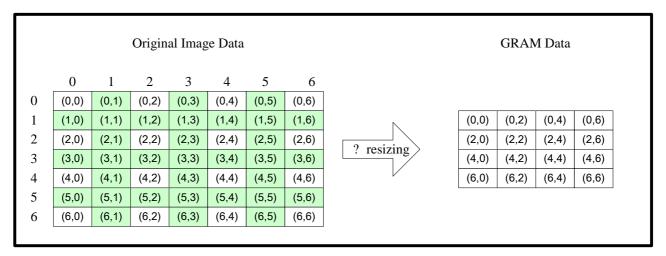

Figure 48 Data transfer in resizing

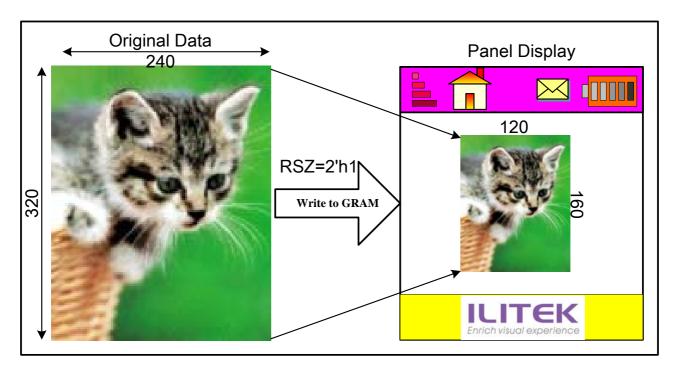

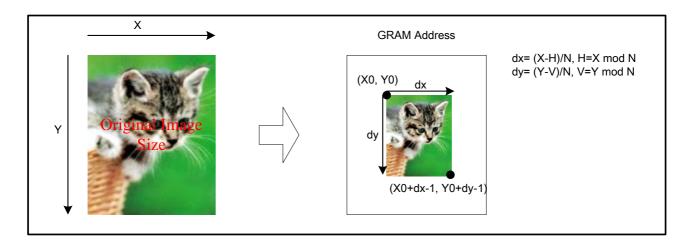

Figure 49 Resizing Example

Original Image Size (X × Y)	Resized Image Resolution				
Original image Size (X ^ 1)	1/2 (RSZ=2'h1)	1/4 (RSZ=2'h3)			
640 × 480	320 × 240	160 × 120			
352 × 288	176 × 144	88 × 72			
320 × 240	160 × 120	80× 60			
176 × 144	88 × 72	44× 36			
120 × 160	60× 80	30 × 40			
132 × 132	66 × 66	33 × 33			

The RSZ bit sets the resizing factor of an image. When setting a window address area in the internal GRAM, the GRAM window address area must fit the size of resized image. The following example show the resizing setting.

Original image data number in horizontal direction		X
Original image data number in Vertical direction		Y
Resizing Ration		1/N
Resizing Setting	RSZ	N-1
Remainder pixels in horizontal direction	RCH	Н
Remainder pixels in vertical direction	RCV	V
GRAM writing start address	AD	(x0, y0)

## 13. Electrical Characteristics

### 13.1. Absolute Maximum Ratings

The absolute maximum rating is listed on following table. When ILI9328 is used out of the absolute maximum ratings, the ILI9328 may be permanently damaged. To use the ILI9328 within the following electrical characteristics limit is strongly recommended for normal operation. If these electrical characteristic conditions are exceeded during normal operation, the ILI9328 will malfunction and cause poor reliability.
